## The Mole Concept

## Counting by weighing

The size of molecule is so small that it is physically difficult if not impossible to directly count out molecules. this problem is solved using a common trick. Atoms and molecules are counted indirectly by weighing.
Here is a practical example. You need to estimate the number of nails in a box. You weigh an empty box, 213. g. The weight of the box plus nails is 1340 . g . The weight of one nail is 0.450 g .

I hope you aren't going to tear open the package and count the nails. We agree that

$$
\begin{aligned}
& \text { mass of nails }=1340 \mathrm{~g}-213 \mathrm{~g}=1227 . \mathrm{g} \\
& \text { Number of nails }=(1227 . \text { grams nails })(1 \text { nail } / 0.450 \text { grams }) \\
&=2726.6 \text { nails }=2730 \text { nails }
\end{aligned}
$$

You can count the nails by weighing them.

## Avogadro's Number and the Mole

To calculate real chemical reactions in the laboratory, chemists use a special unit called a mole (abbreviated mol). One mole of a substance is the amount of the substance that is equal in molar mass of the molecular or formula mass of the substance in grams. Thus for ethylene, $\mathrm{C}_{2} \mathrm{H}_{4}$, its molecular weight is 28 and its molar mass is 28 g . In other words, 28 g represents 1 mol of ethylene. One mole contains $6.022 \times 10^{23}$ molecules or formula units. The number $6.022 \times 10^{23}$ is called Avogadro's number.

> For ethylene, $\mathrm{C}_{2} \mathrm{H}_{4}$,
> Molecular mass $\mathrm{C}_{2} \mathrm{H}_{4}=28$
> Molar mass $\mathrm{C}_{2} \mathrm{H}_{4}=28.0 \mathrm{~g}$
> $1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{4}$ contains $6.022 \times 10^{23}$ molecules

The coefficients of a balanced chemical equation indicate the number of moles of each substance in the reaction. Thus, at the level of moles:

$$
\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2}-------\rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}
$$

One mole of propane reacts with five moles of oxygen to form three moles of carbon dioxide and four moles of water.
Avogadro's number is an accident of nature. It is the number of particles that delivers a mole of a substance. Avogadro's number $=6.022 \times 10^{23}$.
The reason why the value is an accident of nature is that the mole is tied to the gram mass unit.
The gram is a convenient mass unit because it matches human sizes. If we were a thousand times greater in size ( like Paul Bunyan) we would find it handy to use kilogram amounts. This means the kilogram mole would be convenient. The number of particles handled in a kilogram mole is 1000

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

times greater. The kilo Avogadro number for the count of particles in a kilomole is $6.022 \times 10^{26}$. If humans were tiny creatures (like Lilliputians) only $1 / 1000$ our present size, milligrams would be more convenient. This means the milligram mole would be more useful. The number of particles handled in a milligram mole (millimole) would be $1 / 1000$ times smaller. The milli Avogadro number for the count of particles in a millimole is $6.022 \times 10^{20}$.

## Molecular Mass and Mass Percent Activity

It is very helpful to think about chemical reactions in molecular terms. However, it is not practical to carry out reactions at the molecular level.

$$
1 \mathrm{C}_{2} \mathrm{H}_{4} \text { molecule }+1 \mathrm{HCl} \text { molecule } 1 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl} \text { molecule }
$$

Because it is not practical to count individual molecules, chemists use ratios of the masses of molecules to carry out reactions. Mass ratios are determined by using the molecular masses of the substances involved in a reaction.

Molecular mass provides the mass ratio we need for carrying out reactions. The mass ratio of one HCl molecule to one ethylene molecule is 36.5 to 28 in the following equation.

$$
\mathrm{C}_{2} \mathrm{H}_{4}+\mathrm{HCl}-\cdots-\cdots-\cdots \rightarrow----\rightarrow \quad \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}
$$

More useful, however, is the fact that the mass ratio in grams is also 36.5 to 28.0 . If we were to combine 36.5 g HCl with 28 g ethylene in the laboratory, they would react in a $1: 1$ molecular ratio.

## Molar mass for elements

You are able to read the periodic table and determine the average atomic mass for an element like carbon. The average mass is 12 . This is a ridiculously tiny number of grams. It is too small to handle normally.

The molar mass of carbon is defined as the mass in grams that is numerically equal to the average atomic weight. This means

1 mole carbon $=12.0$ grams carbon.
This is the mass of carbon that contains $6.022 \times 10^{23}$ carbon atoms. Avogadro's number is 6.022 x $10^{23}$ particles.

This same process gives us the molar mass of any element.
1 mole neon $=20$ grams neon, Ne
1 mole sodium = 23 grams sodium, Na

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

## Molar Mass for Compound

The formulas for compounds are familiar to you. You know the formula for water is $\mathrm{H}_{2} \mathrm{O}$. It should be reasonable that the weight of a formula unit can be calculated by adding up the weights for the atoms in the formula.

The formula weight for water $=$ weight from hydrogen + weight from oxygen
The formula weight for water $=2 \mathrm{H}$ atoms $\times 1 .+1 \mathrm{O}$ atom $\times 16 .=18$.
The molar mass for water $=18$. grams water.

## Example 1.

What is the molar mass for sulfur dioxide, $\mathrm{SO}_{2}(\mathrm{~g})$, a gas used in bleaching and disinfection processes.

1. Look up the atomic weight for each of the elements in the formula.

$$
1 \text { sulfur atom }=32 \quad 1 \text { oxygen atom }=16
$$

2. Count the atoms of each element in the formula unit. one sulfur atom ; two oxygen atoms
3. The formula weight $=$ weight from sulfur + weight from oxygen
4. The formula weight $=1$ sulfur atom $\mathrm{x}(32)+2$ oxygen atoms $\times(16)$
5. The formula weight $\mathrm{SO}_{2}=32+32 .=64$
6. The molar mass $\mathrm{SO}_{2}=64$ grams $\mathrm{SO}_{2}$

Example 2: The formula for methane the major component in natural gas is $\mathrm{CH}_{4}$.
The formula weight for methane $=$ weight from hydrogen + weight from carbon
The formula weight for methane $=4 \mathrm{H}$ atoms $\times 1 .+1 \mathrm{C}$ atom $\times 12 .=16$.
The molar mass for methane $\mathbf{= 1 6 . 0}$ grams methane
Example 3: The formula for ethyl chloride is $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Cl}$.
The formula weight $=$ weight from hydrogen + weight from carbon + weight from chlorine
The formula weight $=5 \mathrm{H}$ atoms $\times 1.0+2 \mathrm{C}$ atom $\times 12.0+1 \mathrm{Cl}$ atom $\times 35.5=64.5$
The molar mass for ethyl chloride $=\mathbf{6 4 . 5}$ grams

## Mole, Molar Mass and Mass Conversions

## Example.

How many grams of hydrogen are needed to give 3. moles of hydrogen?

1. Calculate the molar mass for hydrogen. Look up the atomic weight/mass in the periodic table The molar mass for hydrogen is 1 mole $\mathrm{H}_{2}=2$ grams $\mathrm{H}_{2}$

## For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com

2. determine the mass needed to provide 3 . moles of hydrogen.

1 mole $\mathrm{H}_{2}=2.0$ grams $\mathrm{H}_{2}$;
2 mole $\mathrm{H}_{2}=4.0$ grams $\mathrm{H}_{2}$
3 mole $\mathrm{H}_{2}=6.0$ grams $\mathrm{H}_{2}$
The practical way is to multiply the molar mass by the number of moles. This converts mole to grams
$\left(3\right.$ mole $\left.\mathrm{H}_{2}\right)\left(2\right.$ grams $\mathrm{H}_{2} / 1$ mole $\left.\mathrm{H}_{2}\right)=6$ grams $\mathrm{H}_{2}$

## Example.

How many moles of water are in a liter of water? Assume 1 liter $=1$ kilogram water

1. Calculate the formula weight(mass) for water, $\mathrm{H}_{2} \mathrm{O}$.

Look up the atomic weights in the periodic table for H and O .
The atomic weight for hydrogen is 1
The atomic weight for oxygen is 16
2. Add up the masses from all the atoms in the formula

The formula weight for water is $1+1+16=18$
3. Determine the molar mass for water. Molar mass is a mass in grams that is numerically the same as the formula weight.

1 mole $\mathrm{H}_{2} \mathrm{O}=18.0$ grams $\mathrm{H}_{2} \mathrm{O}$
4. Convert 1000 grams of water to moles. The "conversion factor" is the molar mass.
$\left(1000\right.$ grams $\left.\mathrm{H}_{2} \mathrm{O}\right)\left(1\right.$ mole $\mathrm{H}_{2} \mathrm{O} /$ 18. grams $\left.\mathrm{H}_{2} \mathrm{O}\right)=55.55$ moles $\mathbf{H}_{2} \mathrm{O}$

## Example.

How many moles of sulfur dioxide, $\mathrm{SO}_{2}(\mathrm{~g})$, are in 2000 grams of the gas?

1. Look up the atomic weights in the periodic table for S and O .

The atomic weight for sulphur is 32
The atomic weight for oxygen is 16
2. Calculate the formula weight for $\mathrm{SO}_{2}$. Add up the masses from all the atoms in the formula

The formula weight for sulfur dioxide is $32 \mathrm{~S}+2 \times(16 \mathrm{O})=64 \mathrm{SO}_{2}$
3. Determine the molar mass. Molar mass is a mass in grams that is numerically the same as the formula weight.

1 mole $\mathrm{SO}_{2}=64$. grams $\mathrm{SO}_{2}$

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

4. Convert 2000 grams of $\mathrm{SO}_{2}$ to moles. The "conversion factor" is the molar mass.
(2000 grams $\left.\mathrm{SO}_{2}\right)\left(1\right.$ mole $\mathrm{SO}_{2} / 64$. grams $\left.\mathrm{SO}_{2}\right)=\mathbf{3 1 . 2 5}$ moles $\mathrm{SO}_{2}$,

## Chemical Equations and Mole Relationships

The balanced equations are a chemists recipe for producing a product from reactants. The equation tell us the amounts of reactants needed and the amount of product formed. Balanced equations can be viewed at three levels. The first is the molecular level. The second is the mole level. The third is in terms of masses. We will look at mole relationships here.
These interpretations of chemical equations are of value because they enable us to make predictions about the outcome of reactions.

## Example:

Burning carbon and carbon containing compounds in air can produce carbon monoxide. Carbon monoxide is poisonous. It is cumulative and even if it doesn't kill it can cause chronic illness and brain damage.

$$
2 \mathrm{C}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g})---->2 \mathrm{CO}(\mathrm{~g})
$$

This equation can be viewed in terms of the atomic and molecular level. Two atoms of carbon must react with one molecule of oxygen. Two molecules of carbon monoxide are produced.

The coefficients in the balanced equation tell the moles of each substance involved in the equation

2 moles C $\quad 1$ mole $\mathrm{O}_{2} \quad 2$ moles CO

The mole ratios for this equation are

$$
\mathrm{C}: \mathrm{O}: \mathrm{CO}
$$

$$
2 \text { moles : } 1 \text { mole : } 2 \text { moles }
$$

The reaction between nitrogen and oxygen to produce nitrogen dioxide is analyzed here.

The equation is $\mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g})--->2 \mathrm{NO}_{2}(\mathrm{~g})$

## Mole ratios

1 mole $\mathrm{N}_{2}: 2$ moles $\mathrm{NO}_{2}$
Exercise: What is the mol ratio for nitrogen to oxygen? Answer: $\mathbf{1}$ mole $\mathbf{N}_{2}: \mathbf{2}$ moles $\mathbf{O}_{2}$

## Stoichiometry: Chemical Arithmetic

In the laboratory, it is often necessary to convert between moles and mass of a substance. This relationships is called stoichiometry.

Example:
How many grams of carbon are required to react completely with $100 \mathrm{~g} \mathrm{Fe}_{2} \mathrm{O}_{3}$ ?

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

$$
\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{C}(\mathrm{~s}) 2 \mathrm{Fe}(\mathrm{l})+3 \mathrm{CO}(\mathrm{~g})
$$

Step 1: Write a balanced chemical equation (or check to see that a given equation is balanced). In this case, a balanced chemical equation was given. Organize the information in the problem. It's often helpful to write the amounts given underneath the balanced chemical equation.

$$
\begin{aligned}
& \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{C}(\mathrm{~s})-----------2 \mathrm{Fe}(\mathrm{l})+3 \mathrm{CO}(\mathrm{~g}) \\
& 100 \mathrm{~g} \quad ? \mathrm{~g}
\end{aligned}
$$

Step 2: Convert grams of a given substance to moles. Remember that substances react in terms of their mole ratios, not their mass ratios. To convert grams of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ to moles, we need to know the molar mass of this compound.
$2 \times 56$. g for each mol $\mathrm{Fe}+3 \times 16.0 \mathrm{~g}$ for each mol O

$$
=160 \mathrm{~g} / \mathrm{mol}
$$

Step 3: Use coefficients in the balanced chemical equation to find the mole ratio. Relate moles of what you were given to moles of what you are determining using the mole ratio.

Step 4: Convert moles to grams using molar mass as a conversion factor. It's always a good idea to check to make sure you have answered the question you were asked. Here you were asked to calculate grams of carbon. Another step or two would be necessary if you had been asked to report your answer in some other unit, such as kg.

For the balanced equation:

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

Moles of B

Volume of solution of B

## GIVEN

Use molarity as a conversion factor

Use coefficients in the balanced equation to find mole ratios

Use molarity as a conversion factor FIND

## Reactions with Limiting Amount of

 ReactantsIn actual chemical reactions, one or more reactants may be in excess. The limiting reactant will be consumed completely and limit the amount of product formed. The following exercise provides a simplified view of how limiting reactants affect a chemical reaction.

Example:
$30 \mathrm{~g} \mathrm{NO}_{2}$ and $10 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ react as shown below.

$$
\begin{gathered}
3 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})--------------\rightarrow 2 \mathrm{HNO}_{3}(\mathrm{l})+ \\
\mathrm{NO}(\mathrm{~g})
\end{gathered}
$$

## What is the limiting reactant?

When two or more reactants are present, one reactant must be limiting. To determine which reactant is limiting, we need to look at the mole ratio of the

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

reactants involved.

$$
\begin{aligned}
& 30.0 \mathrm{~g} \mathrm{NO}_{2}\left(\frac{1 \mathrm{~mol} \mathrm{NO}_{2}}{46.0 \mathrm{~g}}\right)=0.652 \mathrm{~mol} \mathrm{NO}_{2} \\
& 10.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}\left(\frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.0 \mathrm{~g}}\right)=0.555 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

The mole ratio of the two reactants is

$$
0.652 \mathrm{~mol} \mathrm{NO}_{2} / 0.555 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}=1.17
$$

According to the stoichiometry of the balanced equation, the mole ratio should be

$$
3 \mathrm{~mol} \mathrm{NO}_{2} / 1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}=3 .
$$

We see that there is not enough $\mathrm{NO}_{2}$, and thus $\mathrm{NO}_{2}$ is the limiting reactant. $\mathrm{H}_{2} \mathrm{O}$ is the excess reactant.

## b. What amount of $\mathrm{HNO}_{3}$ forms under these conditions?

Once the limiting reactant is consumed, no additional product can be formed. We therefore use the limiting reactant to calculate the amount of product.

$$
0.652 \mathrm{~mol} \mathrm{NO}_{2}\left(\frac{2 \mathrm{~mol} \mathrm{HNO}_{3}}{3 \mathrm{~mol} \mathrm{NO}_{2}}\right)\left(63.05 \mathrm{~g} / \mathrm{mol} \mathrm{HNO}_{3}\right)=27.4 \mathrm{~g} \mathrm{HNO}_{3}
$$

## c. What amount of $\mathrm{NO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ remain?

All of the limiting reactant is consumed, so no $\mathrm{NO}_{2}$ remains. Stoichiometry will allow us to calculate the amount of $\mathrm{H}_{2} \mathrm{O}$ remaining by first determining how much $\mathrm{H}_{2} \mathrm{O}$ reacts.

$$
\begin{aligned}
& 0.652 \mathrm{~mol} \mathrm{NO}_{2}\left(\frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{3 \mathrm{~mol} \mathrm{NO}_{2}}\right)\left(18.0 \mathrm{~g} / \mathrm{mol} \mathrm{H}_{2} \mathrm{O}\right)=3.91 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \text { reacts with } 30 \mathrm{~g} \mathrm{NO}_{2} \\
& 10.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \text { available }-3.91 \mathrm{~g} \text { reacted }=6.09 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \text { remaining }
\end{aligned}
$$

### 3.5 Yields of Chemical Reactions

In the previous section, it was assumed that the reactions proceed "to completion,"-in other words, that all reactants are converted to products. However, this is not always the case. Side reactions can result in the formation of secondary products. Chemists calculate the percent yield of a reaction by comparing the amount of product formed to the theoretical yield predicted from stoichiometry.

$$
\text { Percent yield }=\frac{\text { Actual yield of product }}{\text { Theoretica yield of product }} \times 100 \%
$$

Example: What is the theoretical yield of $\mathrm{Al}_{2} \mathrm{~S}_{3}$ when 10.0 g of aluminum is reacted with excess sulfur according to the equation below?

$$
2 \mathrm{Al}(\mathrm{~s})+3 \mathrm{~S}(\mathrm{~s}) \mathrm{Al}_{2} \mathrm{~S}_{3}(\mathrm{~s})
$$

First, we need to convert grams of aluminum to moles:

$$
10.0 \mathrm{~g} \mathrm{~A}\left(\frac{1 \mathrm{~mol} \mathrm{Al}}{26.98 \mathrm{~g}}\right)=0.3706 \mathrm{~mol} \mathrm{Al}
$$

Next, we relate moles of aluminum to moles of product using the stoichiometric coefficients as a mole ratio:

$$
0.3706 \mathrm{~mol} \mathrm{Al}\left(\frac{1 \mathrm{~mol} \mathrm{Al}_{2} \mathrm{~S}_{3}}{2 \mathrm{~mol} \mathrm{Al}}\right)=0.1853 \mathrm{~mol} \mathrm{Al}_{2} \mathrm{~S}_{3}
$$

Finally, we calculate our theoretical yield of Al2S3 in grams.

$$
0.1853 \mathrm{~mol} \mathrm{Al}_{2} \mathrm{~S}_{3}\left(\frac{150.17 \mathrm{~g}}{1 \mathrm{~mol} \mathrm{Al}_{2} \mathrm{~S}_{3}}\right)=27.8 \mathrm{~g} \mathrm{Al}_{2} \mathrm{~S}_{3}
$$

Example: A student performing the reaction above collected 18.7 g Al2S3. What is her percent yield?

$$
\text { Percent yield }=\left(\frac{18.7 \mathrm{~g}}{27.8 \mathrm{~g}}\right) \times 100=62.7 \% \text { yield }
$$

## Percent Yield

The percent yield is defined as

The predicted yield is determined by the masses used in a reaction and the mole ratios in the balanced equation. This predicted yield is the "ideal". It is not always possible to get this amount

## For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com

of product. Reactions are not always simple. There often are competing reactions. For example, if you burn carbon in air you can get carbon dioxide and carbon monoxide formed. The two reactions occur simultaneously. Some carbon atoms end up in CO and others end up in $\mathrm{CO}_{2}$

## Example:

What is the percent yield for a reaction if you predicted the formation of 21 . grams of $\mathrm{C}_{6} \mathrm{H}_{12}$ and actually recovered only 3.8 grams?

1. Recall definition of percent yield. Percent yield $=\mathbf{1 0 0}$

## actual yield

predicted yield

$$
\text { Percent yield }=100\left[\frac{3.8 \mathrm{~g}}{21 \mathrm{~g}}\right]
$$

3. Answer: The percent yield is $18 \%$.

## Example:

A reaction between solid sulfur and oxygen produces sulfur dioxide.
The reaction started with 384 grams of $S_{6}(\mathrm{~s})$. Assume an unlimited supply of oxygen. What is the predicted yield and the percent yield if only 680 grams of sulfur dioxide are produced?

Step 1 : Calculate the molar masses for $\mathrm{S}_{6}(\mathrm{~s})$ and $\mathrm{SO}_{2}(\mathrm{~g})$. The oxygen has no effect on the answer because there is more than you need.

1 mole $\mathrm{S}_{6}(\mathrm{~s})=193$ grams $\mathrm{S}_{6}(\mathrm{~s}) ; 1$ mole $\mathrm{SO}_{2}(\mathrm{~g})=64$ grams $\mathrm{SO}_{2}(\mathrm{~g})$
Step 2 : Mole ratio method
Determine the mole ratio for 1 mole $^{\mathrm{S}_{6}}(\mathrm{~s})$ to $\mathrm{mole}^{\mathrm{SO}_{2}}(\mathrm{~g})$
The balanced equation indicates 1 mole $\mathrm{S}_{6}(\mathrm{~s})$ to $6{\text { mole } \mathrm{SO}_{2}(\mathrm{~g})}^{(\mathrm{g}}$ )
Step 3: Calculate the number of moles of $S_{6}(\mathrm{~s})$

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

$\operatorname{moles} \mathrm{S}_{6}(\mathrm{~s})=\left[384 \mathrm{~g} \mathrm{~S}_{6}(\mathrm{~s})\right]\left[1\right.$ mole $\left.\mathrm{S}_{6}(\mathrm{~s}) / 192 \mathrm{~g} \mathrm{~S} 6(\mathrm{~s})\right]=2$ moles $\mathrm{S}_{6}(\mathrm{~s})$
Step 4: Calculate the moles of $\mathrm{SO}_{2}(\mathrm{~g})$ expected using the mole ratio $6 \mathrm{SO}_{2}(\mathrm{~g}) / 1 \mathrm{~S}_{6}(\mathrm{~s})$
moles $\mathrm{SO}_{2}(\mathrm{~g})=2$ moles $\mathrm{S}_{6}(\mathrm{~s})\left[6 \mathrm{SO}_{2}(\mathrm{~g}) / 1 \mathrm{~S}_{6}(\mathrm{~s})\right]=12$ moles $\mathrm{SO}_{2}(\mathrm{~g})$

Step 5: Calculate the grams of $\mathrm{SO}_{2}(\mathrm{~g})$ predicted using 1 mole $\mathrm{SO}_{2}(\mathrm{~g})=64$ grams $\mathrm{SO}_{2}(\mathrm{~g})$
grams $\mathrm{SO}_{2}(\mathrm{~g})=12$ moles $\mathrm{SO}_{2}(\mathrm{~g})\left[64\right.$ grams $\mathrm{SO}_{2}(\mathrm{~g}) / 1$ mole $\left.\mathrm{SO}_{2}(\mathrm{~g})\right]=768 \mathrm{~g} \mathrm{SO}_{2}(\mathrm{~g})$
Step 6: Calculate the percent yield using the definition
Percent yield $=100[$ actual yield $/$ predicted yield $]=100\left[680\right.$ grams $\left.\mathrm{SO}_{2}(\mathrm{~g}) / 768 \mathrm{~g} \mathrm{SO}_{2}(\mathrm{~g})\right]=89 \%$

## Concentrations of Reactants in Solution: Moles/dm ${ }^{\mathbf{3}}$ (Molarity)

Many chemical reactions occur in solution. In order to make stoichiometric calculations for these reactions, we need to be able to express the concentration of reactants in solution. One of the most useful concentration units is moles $/ \mathrm{dm}^{3}$ (molarity abbreviated M). Using moles $/ \mathrm{dm}^{3}$ as a conversion factor is quite useful.

$$
\text { Molarity }(\mathbf{M})=\frac{\text { Moles of solute }}{\text { Liters of solution }}
$$

In the laboratory, solutions are prepared according to several steps. Let's prepare 250 mL of a 0.100 M solution of NaCl . (Unless otherwise noted, solutions are aqueous and water is the solvent.)

First, we have to do a calculation. We need to know how many grams of NaCl to weigh.

$$
\begin{gathered}
0.250 \mathrm{~L}\left(0.100 \mathrm{~mol} \mathrm{NaCl} / \mathrm{dm}^{3} \text { solution }\right) \\
=0.0250 \mathrm{~mol} \mathrm{NaCl}(58.5 \mathrm{~g} / \mathrm{mol}) \\
=1.46 \mathrm{~g} \mathrm{NaCl} .
\end{gathered}
$$

Next, we weigh this amount on a balance and transfer the solid to a 250 mL volumetric flask-a very precise piece of glassware designed to contain only a specific volume of liquid.

Finally, we add our solvent - in this case, water-to the flask. First, we add a small amount to dissolve the solute. Then we add water up to the calibration mark on the flask and mix well.

# For Live Classes, Recorded Lectures, Notes \& Past Papers visit: www.megalecture.com 

## Solution Stoichiometry

Moles $/ \mathrm{dm}^{3}$ serves as a useful link between the volume of a solution and the number of moles of a solute. The flow diagram below summarizes the steps in stoichiometry calcuations involving solutions.

Example:
How many mL of a 0.90 M solution of HCl is required to react with $4.16 \mathrm{~g} \mathrm{CaCO}_{3}$, according to the equation below?

$$
\begin{gathered}
\mathrm{CaCO}_{3}(\mathrm{~s})+\underset{\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})}{2 \mathrm{HCl}(\mathrm{aq})-\cdots---} \mathrm{CaCl}_{2}(\mathrm{aq})+ \\
\mathrm{Cl}^{2}
\end{gathered}
$$

In this problem, we are given the concentration of the HCl solution. We are given a mass in grams of one of the reactants. So our first step is to convert mass to moles.

$$
\begin{gathered}
4.16 \mathrm{~g} \mathrm{CaCO}_{3}(1 \mathrm{~mol} / 100 \mathrm{~g})=4.16 \times 10^{-2} \mathrm{~mol} \\
\mathrm{CaCO}_{3}
\end{gathered}
$$

Next, we relate moles of $\mathrm{CaCO}_{3}$ to moles of HCl required using the coefficients in the balanced equation. The reaction ratio is $2: 1$ respectively
$4.16 \times 10^{-2} \mathrm{~mol} \mathrm{CaCO}_{3}(2 \mathrm{~mol} \mathrm{HCl} / 1 \mathrm{~mol}$ $\left.\mathrm{CaCO}_{3}\right)=8.31 \times 10^{-2} \mathrm{~mol} \mathrm{HCl}$

Now we can convert moles of HCl to volume of HCl using the moles $/ \mathrm{dm}^{3}$.

$$
8.31 \times 10^{-2} \mathrm{~mol} \mathrm{HCl}\left(1 \mathrm{dm}^{3} \text { solution } / 0.90 \mathrm{~mol} \mathrm{HCl}\right)=9.23 \times 10^{-2} \mathrm{~L} \mathrm{HCl} \text { solution }
$$ $9.23 \times 10^{-2} \mathrm{~L}(1000 \mathrm{~mL} / \mathrm{L})=92.3 \mathrm{~mL} \mathrm{HCl}$ solution
