

Formulas

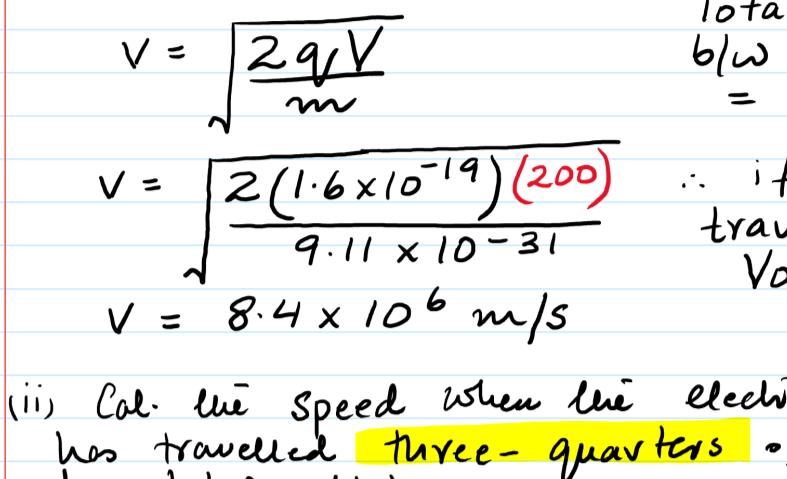

$$\textcircled{1} \quad E = \frac{V}{d}$$

$$\textcircled{2} \quad E = \frac{F}{q}$$

$$\textcircled{3} \quad V = \frac{W}{q}$$

$$\textcircled{4} \quad V = \sqrt{\frac{2qV}{m}}$$

Note: How else can we use the velocity formula i.e. $V = \sqrt{\frac{2qV}{m}}$

i) Cal. the speed when the electron is midway b/w the 2 plates A & B

$$V = \sqrt{\frac{2qV}{m}}$$

$$\text{Total p. diff. b/w the plates} = 400 \text{ V}$$

$$V = \sqrt{\frac{2(1.6 \times 10^{-19})(200)}{9.11 \times 10^{-31}}} \quad \dots \text{if } e^- \text{ has travelled midway}$$

$$\text{Voltage} = 200 \text{ V}$$

ii) Cal. the speed when the electron has travelled three-quarters of the total distance

$$V = \sqrt{\frac{2(1.6 \times 10^{-19})(300)}{9.11 \times 10^{-31}}} \quad \text{Voltage} = 300 \text{ V}$$

$$V = 1.02 \times 10^7 \text{ m/s.}$$

Ex. four charges Na^{+} , Ca^{2+} , α , e^{-}

all four charges are released simultaneously; which charge particle will reach the opposite plate with greatest velocity? constant

formula $V = \sqrt{\frac{2qV}{m}}$

Since all charges will accelerate through the same voltage $\therefore V = \text{constant}$

note: velocity will only depend upon $\sqrt{\frac{q}{m}}$.

$V \propto \sqrt{\frac{q}{m}}$

[velocity will depend on the ratio of charge (q/m) mass]

Sodium Na^{+}

$$\sqrt{\frac{1}{23}}$$

$$\text{Alpha } \alpha \sqrt{\frac{2}{4}}$$

Calcium Ca^{2+}

$$\sqrt{\frac{2}{40}}$$

$$\text{Electron } e^{-} \sqrt{\frac{1}{1840}}$$

Answer: electron

Ex. for the same charges, calculate which particle will have greatest momentum?

$$\text{momentum} = \text{mass} \times \text{velocity}$$

$$= m \times \sqrt{\frac{2qV}{m}}$$

Simplify to get

$$\text{momentum} = \sqrt{2qmV}$$

Since Voltage V = constant \therefore momentum depends upon the product of mass & charge i.e. momentum $\propto \sqrt{m \cdot q}$.

$$\text{Na}^{+} = \sqrt{23 \times 1} \quad \alpha = \sqrt{4 \times 2}$$

$$\text{Ca}^{2+} = \sqrt{40 \times 2} \quad e^{-} = \sqrt{\frac{1}{1840} \times 1}$$

Ans.: Calcium

Ex. The distance b/w the two plates A and B is now doubled i.e.

from 5cm to 10cm. Suggest what happens to the final velocity of the electron if it now travels b/w the 2 plates?

Previous:

new:

$V = \sqrt{\frac{2qV}{m}}$

velocity depends on

Voltage, q & m. Since

it does not depend on

the distance b/w the plates \therefore final velocity

remains unchanged.

Lengthy explanation:

$$\textcircled{1} \quad E = \frac{V}{d} \rightarrow \text{double}$$

$$V^2 = u^2 + 2as$$

half \downarrow double
so cancels out

$$\textcircled{2} \quad F = Eq \rightarrow \text{half}$$

$$\therefore \text{velocity / speed remains unchanged.}$$

$$\textcircled{3} \quad F = ma \rightarrow \text{half}$$

$$\text{acceptable explanation.}$$

(vi) Sketch the following graphs for the electron moving from one plate to the other.

(i) Velocity - time

$$\text{grad} = \text{acc.}$$

$$E = \text{uniform}$$

$$F = Eq$$

$$F = \text{const.}$$

$$F = ma$$

$$a = \text{const.}$$

(straight-line)

$$V^2 = u^2 + 2as$$

since $u = 0$ b/c

electron started from rest.

$$V^2 = 2as$$

$$a = \text{constant}$$
